Chapter 1

Introduction

1.1 Computational Linguistics: Course Overview

In this class, we will study:

1. Formal Language Theory
2. Automata Theory
3. Haskell
4. ... as they pertain to problems in linguistics:
 - (a) *Well-formedness* of linguistic representations
 - (b) *Transformations* from one representation to another

1.1.1 Linguistic Theory

Linguistic theory often distinguishes between *well-* and *ill-formed representations*.

Strings. In English, we can coin new words like *bling*. What about the following?

1. *gding*
2. *θwik*
3. *spif*

Trees. In English, we interpret the compound *deer-resistant* as an adjective, not a noun. What about the following?

1. *green-house*
2. *dry-clean*
3. *over-throw*

Linguistic theory is often also concerned with *transformations*.

Strings. In generative phonology, underlying representations of words are *transformed* to surface representations of words.

1. $/kæt-z/ \rightarrow [kæts]$
2. $/wɪf-z/ \rightarrow [wɪfɪz]$

Trees. In derivational theories of generative syntax, the deep sentence structure is *transformed* into a surface structure.

1. Mary won the competition.
 - (a) The competition was won by Mary.
 - (b) What did Mary win?

1.1.2 Automata Theory

Automata are *abstract* machines that answer questions like these.

The Membership Problem

Given: A possibly infinite set of strings (or trees) X .

Input: A input string (or tree) x .

Problem: Does x belong to X ?

The Transformation Problem

Given: A possible infinite function of strings to strings (or trees to trees) $f : X \rightarrow Y$.

Input: A input string (or tree) x .

Problem: What is $f(x)$?

There are many kinds of automata. Two common types of automata address these specific problems.

Recognizers Recognizers solve the membership problem.

Transducers Transducers solve the transformation problem.

Different kinds of automata instantiate different kinds of memory.

Finite-state Automata An automata is finite-state whenever the amount of memory necessary to solve a problem for input x is fixed and **independent** of the size of x .

Linear-bounded Automata An automata is linear-bounded whenever the amount of memory necessary to solve a problem for input x is **bounded by a linear function** of the size of x .

In this class we will study finite-state recognizers and transducers. There are many types of these as well, some are shown below.

- deterministic vs. non-deterministic
- 1way vs. 2way (for strings)
- bottom-up vs. top-down vs. walking (for trees)

The simplest type is the deterministic, 1way recognizer for strings. We will start there and then complicate them bit by bit:

1. add non-determinism
2. add output (transducers)
3. add 2way-ness
4. generalize strings to trees and repeat

What do automata mean for linguistic theory?

Fact 1: Finite-state automata over strings are sufficient for phonology and morphology (Johnson, 1972; Kaplan and Kay, 1994; Roark and Sproat, 2007; Dolatian and Heinz, 2020).

Fact 2: Finite-state automata over strings are *NOT* sufficient for syntax, but linear-bounded automata are (Chomsky, 1956; Huybregts, 1984; Shieber, 1985, among others).

Fact 3: Finite-state automata over trees *ARE* sufficient for syntax (Rogers, 1998; Kobele, 2011; Graf, 2011; Stabler, 2019).

Hypothesis: Linguistic phenomena can be modeled with special kinds of finite-state automata with even stricter memory requirements over the right representations (Heinz, 2018; Graf and De Santo, 2019; Graf, 2022).

Chapter 2

Formal Language Theory

The material in this chapter is covered in much greater detail in a number of textbooks including McNaughton and Papert (1971); Harrison (1978); Hopcroft *et al.* (1979); Davis and Weyuker (1983); Hopcroft *et al.* (2001) and Sipser (1997). Here we will state definitions and theorems, but we will not cover the proofs of the theorems.

We begin with the following question: If we choose to model natural languages with formal languages, what kind of formal languages are they? We have some idea what natural languages are. After all, you are reading this! A satisfactory answer to answer this question however also requires being clear about what a formal language is.

2.1 Formal Languages

A formal language is a set of strings. Strings are sequences of symbols of finite length. The symbol Σ commonly denotes a finite set of symbols. There is a unique string of length zero, which is the empty string. This is commonly denoted with λ or ϵ .

A key operation on strings is *concatenation*. The concatenation of string x with string y is written xy . Concatenation is associative: for all strings x, y, z , it holds that $(xy)z = x(yz)$. The empty string is an identity element for concatenation: for all strings x , $x\lambda = \lambda x = x$. If we concatenate a string x with itself n times we write x^n . For example, $(ab)^3 = ababab$.

We can also concatenate two formal languages X and Y .

$$XY = \{xy : x \in X, y \in Y\}$$

Language concatenation is also associative. The empty string language $\{\lambda\}$ is an identity element for language concatenation: for all languages L , $L\{\lambda\} = \{\lambda\}L = L$. Also, the empty set \emptyset is a zero element for language concatenation: for all languages L , $L\emptyset = \emptyset L = \emptyset$.

If we concatenate a language X with itself n times we write X^n . For example, $XX = X^2$. Finally for any language X , we define X^* as follows.

$$X^* = \{\lambda\} \cup X \cup X^2 \cup X^3 \dots = \bigcup_{n \geq 0} X^n$$

where X^0 is defined as $\{\lambda\}$. The asterisk ($*$) is called the Kleene star after Kleene (1956) who introduced it.

It follows that the set of all strings of finite length can be denoted Σ^* . Consequently formal languages can be thought of as subsets of Σ^* . How can we talk about such subsets?

One way is to use set notation and set construction. Example 1 present some examples of formal languages defined in these ways.

Example 1. In this example, assume $\Sigma = \{a, b, c\}$.

1. $\{\lambda, a\}$.
2. $\{\lambda, a, aa\}$.
3. $\{a^n \in \Sigma^* : n \leq 10\}$.
4. $\{a^n \in \Sigma^* : n \geq 0\}$.
5. $\{w \in \Sigma^*\}$.
6. $\{w \in \Sigma^* : w \text{ contains the string } aa\}$.
7. $\{w \in \Sigma^* : w \text{ does not contain the string } aa\}$.
8. $\{w \in \Sigma^* : w \text{ contains a } b \text{ somewhere after an } a\}$.
9. $\{w \in \Sigma^* : w \text{ does not contain a } b \text{ somewhere after an } a\}$.
10. $\{w \in \Sigma^* : w \text{ contains either the string } aa \text{ or the string } bb\}$.
11. $\{w \in \Sigma^* : w \text{ contains both the string } aa \text{ and the string } bb\}$.
12. $\{w \in \Sigma^* : w \text{ does not contain the string } bb \text{ on the } \{b, c\} \text{ tier}\}$.
13. $\{w \in \Sigma^* : w \text{ contains an even number of } as\}$.
14. $\{a^n b^n \in \Sigma^* : n \geq 1\}$.
15. $\{a^n b^m \in \Sigma^* : m > n\}$.
16. $\{a^n b^n c^n \in \Sigma^* : n \geq 1\}$.
17. $\{a^n b^m c^\ell \in \Sigma^* : \ell > m > n\}$.
18. $\{w \in \Sigma^* : \text{the number of } bs \text{ is the same as the number of } cs \text{ in } w\}$.
19. $\{w \in \Sigma^* : \text{the number of } as, bs, \text{ and } cs \text{ is the same in } w\}$.
20. $\{a^n \in \Sigma^* : n \text{ is a prime number}\}$.

2.2 Grammars

There are two important aspects to defining grammar formalisms. They are distinct, but related, aspects.

1. The grammar itself. This is an object and in order to be well-formed it has to follow certain rules and/or conditions.
2. How the grammar is associated with a language. A separate set of rules/conditions explains how to *interpret* the grammar. This aspect explains how the grammar *generates/recognizes/accepts* a language.

In other words, by itself, a grammar is more or less useless. But combined with a way to interpret it—a way to associate it with a formal language—it becomes a very powerful form of expression.

2.3 Expression Grammars

As a first example, consider regular expressions. These consist of both a syntax (which define well-formed regular expressions) and a semantics (which associate them unambiguously with formal languages). They are defined inductively.

Syntax	Semantics
REs include	
• each $\sigma \in \Sigma$ (<i>singleton letter set</i>)	$\llbracket \sigma \rrbracket = \{\sigma\}$
• ϵ (<i>empty string set</i>)	$\llbracket \epsilon \rrbracket = \{\epsilon\}$
• \emptyset (<i>empty set</i>)	$\llbracket \emptyset \rrbracket = \{\}$
If R, S are REs then so are:	
• $(R \circ S)$ (<i>concatenation</i>)	$\llbracket (R \cdot S) \rrbracket = \llbracket R \rrbracket \circ \llbracket S \rrbracket$
• $(R + S)$ (<i>union</i>)	$\llbracket (R + S) \rrbracket = \llbracket R \rrbracket \cup \llbracket S \rrbracket$
• (R^*) (<i>Kleene star</i>)	$\llbracket (R^*) \rrbracket = \llbracket R \rrbracket^*$

We say a language is *regular* if there is a regular expression denoting it. The class of regular languages is denoted $\llbracket RE \rrbracket$.

Exercise 1. Write regular expressions for as many of the languages in Example 1 as you can.

2.3.1 Cat-Union Expressions

Syntax	Semantics
CUEs include	
• each $\sigma \in \Sigma$ (<i>singleton letter set</i>)	$\llbracket \sigma \rrbracket = \{\sigma\}$
• ϵ (<i>empty string set</i>)	$\llbracket \epsilon \rrbracket = \{\epsilon\}$
• \emptyset (<i>empty set</i>)	$\llbracket \emptyset \rrbracket = \{\}$

If R, S are CUEs then so are:

- $(R \circ S)$ (*concatenation*) $\llbracket (R \cdot S) \rrbracket = \llbracket R \rrbracket \circ \llbracket S \rrbracket$
- $(R + S)$ (*union*) $\llbracket (R + S) \rrbracket = \llbracket R \rrbracket \cup \llbracket S \rrbracket$

So CUEs are a fragment of REs that exclude Kleene star.

Exercise 2. Write CUEs for as many of the languages in Example 1 as you can. What kinds of formal languages do cat-union expressions describe?

Theorem 1. $\llbracket CUE \rrbracket = \{L \subseteq \Sigma^* : |L| \text{ is finite}\} \subsetneq \llbracket RE \rrbracket$

2.3.2 Generalized Regular Expressions

Syntax	Semantics
GREs include	
• each $\sigma \in \Sigma$ (<i>singleton letter set</i>)	$\llbracket \sigma \rrbracket = \{\sigma\}$
• ϵ (<i>empty string set</i>)	$\llbracket \epsilon \rrbracket = \{\epsilon\}$
• \emptyset (<i>empty set</i>)	$\llbracket \emptyset \rrbracket = \{\}$

If R, S are GREs then so are:

- $(R \circ S)$ (*concatenation*) $\llbracket (R \cdot S) \rrbracket = \llbracket R \rrbracket \circ \llbracket S \rrbracket$
- $(R + S)$ (*union*) $\llbracket (R + S) \rrbracket = \llbracket R \rrbracket \cup \llbracket S \rrbracket$
- (R^*) (*Kleene star*) $\llbracket (R^*) \rrbracket = \llbracket R \rrbracket^*$
- $(R \& S)$ (*intersection*) $\llbracket (R \& S) \rrbracket = \llbracket R \rrbracket \cap \llbracket S \rrbracket$
- (\overline{R}) (*complement*) $\llbracket \overline{R} \rrbracket = \Sigma^* - \llbracket R \rrbracket$

Theorem 2. $\llbracket RE \rrbracket = \llbracket GRE \rrbracket$

Exercise 3. Write GREs for as many of the languages in Example 1 as you can.

2.3.3 Star Free Expressions

Syntax	Semantics
SFEs include	
• each $\sigma \in \Sigma$ (<i>singleton letter set</i>)	$\llbracket \sigma \rrbracket = \{\sigma\}$
• ϵ (<i>empty string set</i>)	$\llbracket \epsilon \rrbracket = \{\epsilon\}$
• \emptyset (<i>empty set</i>)	$\llbracket \emptyset \rrbracket = \{\}$
If R, S are SFEs then so are:	
• $(R \circ S)$ (<i>concatenation</i>)	$\llbracket (R \cdot S) \rrbracket = \llbracket R \rrbracket \circ \llbracket S \rrbracket$
• $(R + S)$ (<i>union</i>)	$\llbracket (R + S) \rrbracket = \llbracket R \rrbracket \cup \llbracket S \rrbracket$
• $(R \& S)$ (<i>intersection</i>)	$\llbracket (R \& S) \rrbracket = \llbracket R \rrbracket \cap \llbracket S \rrbracket$
• (\overline{R}) (<i>complement</i>)	$\llbracket \overline{R} \rrbracket = \Sigma^* - \llbracket R \rrbracket$

So SFEs are a fragment of GREs that exclude Kleene star.

Exercise 4. Write SFEs for as many of the languages in Example 1 as you can.

Theorem 3. $\llbracket CUE \rrbracket \subsetneq \llbracket SFE \rrbracket \subsetneq \llbracket RE \rrbracket = \llbracket GRE \rrbracket$

For more information on the theorems in this section, see McNaughton and Papert (1971).

2.3.4 Piecewise Local Expressions

Dakotah Lambert developed PLEs over the past ten years. His 2022 dissertation provides a written treatment. I present a large fragment of them here (some more details are in the thesis). Part of the motivation for PLEs is to develop linguistically motivated expression-builders.

As an example, Lambert introduces a tier operator which takes two arguments: a set of symbols T (the tier elements) and a language L . Non-tier elements are freely insertable and deleteable (they have no effect on whether a string belongs to the language or not). Removing the non-tier symbols from a word yields a string of symbols on the tier. Given a language L , let us call the language obtained from removing the non-tier symbols from all of its words, the tier-projection of L . Then Lambert's tier operator produces the largest language in Σ^* such that its tier-projection equals the tier-projection of L . Lambert's operator is thus the *maximal, inverse* tier-projection.

Formally, for all $\sigma \in \Sigma$ and all $T \subseteq \Sigma$, let $I_T(\sigma)$ denote the string σ iff $\sigma \in T$ and λ otherwise. Then, for all $w = \sigma_1\sigma_2\ldots\sigma_n \in \Sigma^*$, we let $[T]w$ be the language $S^*I_T(\sigma_1)S^*I_T(\sigma_2)S^*\ldots S^*I_T(\sigma_n)S^*$ where $S = \Sigma - T$. Finally, for any language L , we let $[T]L = \bigcup_w \in L[T]w$.

Syntax		Semantics	
For all $\sigma_1\sigma_2\ldots\sigma_n \in \Sigma^*$ PLEs include			
$\bullet \langle \sigma_1\sigma_2\ldots\sigma_n \rangle$	(unanchored substring)	$\llbracket \langle \sigma_1\sigma_2\ldots\sigma_n \rangle \rrbracket$	$= \Sigma^* \sigma_1\sigma_2\ldots\sigma_n \Sigma^*$
$\bullet \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle$	(unanchored subsequence)	$\llbracket \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle \rrbracket$	$= \Sigma^* \sigma_1 \Sigma^* \sigma_2 \Sigma^* \ldots \Sigma^* \sigma_n \Sigma^*$
$\bullet \bowtie \langle \sigma_1\sigma_2\ldots\sigma_n \rangle$	(left-anchored substring)	$\llbracket \bowtie \langle \sigma_1\sigma_2\ldots\sigma_n \rangle \rrbracket$	$= \sigma_1\sigma_2\ldots\sigma_n \Sigma^*$
$\bullet \bowtie \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle$	(left-anchored subsequence)	$\llbracket \bowtie \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle \rrbracket$	$= \sigma_1 \Sigma^* \sigma_2 \Sigma^* \ldots \Sigma^* \sigma_n \Sigma^*$
$\bullet \bowtie \langle \sigma_1\sigma_2\ldots\sigma_n \rangle$	(right-anchored substring)	$\llbracket \bowtie \langle \sigma_1\sigma_2\ldots\sigma_n \rangle \rrbracket$	$= \Sigma^* \sigma_1\sigma_2\ldots\sigma_n$
$\bullet \bowtie \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle$	(right-anchored subsequence)	$\llbracket \bowtie \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle \rrbracket$	$= \Sigma^* \sigma_1 \Sigma^* \sigma_2 \Sigma^* \ldots \Sigma^* \sigma_n$
$\bullet \bowtie \bowtie \langle \sigma_1\sigma_2\ldots\sigma_n \rangle$	(anchored substring)	$\llbracket \bowtie \bowtie \langle \sigma_1\sigma_2\ldots\sigma_n \rangle \rrbracket$	$= \{\sigma_1\sigma_2\ldots\sigma_n\}$
$\bullet \bowtie \bowtie \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle$	(anchored subsequence)	$\llbracket \bowtie \bowtie \langle \sigma_1, \sigma_2, \ldots, \sigma_n \rangle \rrbracket$	$= \sigma_1 \Sigma^* \sigma_2 \Sigma^* \ldots \Sigma^* \sigma_n$
If $R_1, R_2, \ldots R_n$ are PLEs then so are:			
$\bullet \neg R_1$	(complement)	$\llbracket \neg R_1 \rrbracket$	$= \Sigma^* - \llbracket R_1 \rrbracket$
$\bullet * R_1$	(Kleene star)	$\llbracket * R_1 \rrbracket$	$= \llbracket R_1 \rrbracket^*$
$\bullet [\sigma_1, \sigma_2, \ldots \sigma_n] R_1$	(tier max-inv-projection)	$\llbracket [\sigma_1, \sigma_2, \ldots \sigma_n] R_1 \rrbracket$	$= [\sigma_1, \sigma_2, \ldots \sigma_n] \llbracket R_1 \rrbracket$
$\bullet \wedge \{R_1, R_2, \ldots R_n\}$	(intersection)	$\llbracket \wedge \{R_1, R_2, \ldots R_n\} \rrbracket$	$= \bigcap_{1 \leq i \leq n} \llbracket R_i \rrbracket$
$\bullet \vee \{R_1, R_2, \ldots R_n\}$	(union)	$\llbracket \vee \{R_1, R_2, \ldots R_n\} \rrbracket$	$= \bigcup_{1 \leq i \leq n} \llbracket R_i \rrbracket$
$\bullet \circ \{R_1, R_2, \ldots R_n\}$	(concatenation)	$\llbracket \circ \{R_1, R_2, \ldots R_n\} \rrbracket$	$= \llbracket R_1 \rrbracket \circ \llbracket R_2 \rrbracket \circ \ldots \circ \llbracket R_n \rrbracket$

Theorem 4. $\llbracket CUE \rrbracket \subsetneq \llbracket SFE \rrbracket \subsetneq \llbracket RE \rrbracket = \llbracket GRE \rrbracket = \llbracket PLE \rrbracket$

Exercise 5. Write PLEs for as many of the languages in Example 1 as you can.

2.4 Rewrite Grammars

There are many ways to define grammars which describe formal languages. Another influential approach has been rewrite grammars (Hopcroft *et al.*, 1979).

Definition 1. A rewrite grammar¹ is a tuple $\langle T, N, S, \mathcal{R} \rangle$ where

- \mathcal{T} is a nonempty finite alphabet of symbols. These symbols are also called the terminal symbols, and we usually write them with lowercase letters like a, b, c, \ldots

¹For a slightly different definition and some more description of rewrite grammars, see Partee *et al.* (1993, chap. 16).

- \mathcal{N} is a nonempty finite set of non-terminal symbols, which are distinct from elements of \mathcal{T} . These symbols are also called *category symbols*, and we usually write them with uppercase letters like A, B, C, \dots
- S is the *start category*, which is an element of \mathcal{N} .
- A finite set of production rules \mathcal{R} . A production rule has the form

$$\alpha \rightarrow \beta$$

where α, β belong to $(\mathcal{T} \cup \mathcal{N})^*$. In other words, α and β are strings of non-terminal and terminal symbols. While β may be the empty string we require that α include at least one symbol.

Rewrite grammars are also called *phrase structure grammars*.

Example 2. Consider the following grammar G_1 :

- $\mathcal{T} = \{\textit{john}, \textit{laughed}, \textit{and}\};$
- $\mathcal{N} = \{S, VP1, VP2\};$ and
-

$$\mathcal{R} = \left\{ \begin{array}{l} S \rightarrow \textit{john} VP1 \\ VP1 \rightarrow \textit{laughed} \\ VP1 \rightarrow \textit{laughed} VP2 \\ VP2 \rightarrow \textit{and laughed} \\ VP2 \rightarrow \textit{and laughed} VP2 \end{array} \right\}$$

Example 3. Consider the following grammar G_2 :

- $\mathcal{T} = \{a, b\};$
- $\mathcal{N} = \{S, A, B\};$ and
-

$$\mathcal{R} = \left\{ \begin{array}{l} S \rightarrow ABS \\ S \rightarrow \lambda \\ AB \rightarrow BA \\ BA \rightarrow AB \\ A \rightarrow a \\ B \rightarrow b \end{array} \right\}$$

Example 4. Consider the following grammar G_3 :

- $\mathcal{T} = \{a, b\};$
- $\mathcal{N} = \{S\};$ and

•

$$\mathcal{R} = \left\{ \begin{array}{l} S \rightarrow ba \\ S \rightarrow baba \\ S \rightarrow bab \end{array} \right\}$$

The language of a rewrite grammar is defined recursively below.

Definition 2. The (partial) derivations of a rewrite grammar $G = \langle \mathcal{T}, \mathcal{N}, S, \mathcal{R} \rangle$ is written $D(G)$ and is defined recursively as follows.

1. The base case: S belongs to $D(G)$.
2. The recursive case: For all $\alpha \rightarrow \beta \in \mathcal{R}$ and for all $\gamma_1, \gamma_2 \in (\mathcal{T} \cup \mathcal{N})^*$, if $\gamma_1 \alpha \gamma_2 \in D(G)$ then $\gamma_1 \beta \gamma_2 \in D(G)$.
3. Nothing else is in $D(G)$.

Then the language of the grammar $L(G)$ is defined as

$$L(G) = \{w \in \mathcal{T}^* : w \in D(G)\}.$$

Exercise 6. How does G_1 generate *John laughed and laughed and laughed*?

Exercise 7. What language does G_2 generate?

Exercise 8. What language does G_3 generate?

2.5 The Chomsky Hierarchy

“By putting increasingly stringent restrictions on the allowed forms of rules we can establish a series of grammars of decreasing generative power. Many such series are imaginable, but the one which has received the most attention is due to Chomsky and has come to be known as the Chomsky Hierarchy.” (Partee *et al.*, 1993, p. 451)

Recall that rules are of the form $\alpha \rightarrow \beta$ with $\alpha, \beta \in (\mathcal{T} \cup \mathcal{N})^*$, with the further restriction that α was not the empty string.

Type 0 There is no further restriction on α or β .

Type 1 Each rule is of the form $\alpha \rightarrow \beta$ where α contains at least one symbol $A \in \mathcal{N}$ and β is not the empty string.

Type 2 Each rule is of the form $A \rightarrow \beta$ where $A \in \mathcal{N}$ and $\beta \in (\mathcal{T} \cup \mathcal{N})^*$.

Type 3 Each rule is of the form $A \rightarrow aB$ or $A \rightarrow a$ where $A, B \in \mathcal{N}$ and $a \in \mathcal{T}$.

There is one exception to the above restrictions for Types 1, 2 and 3. For these types, the production $S \rightarrow \lambda$ is allowed. If this production is included in a grammar then the formal language it describes will include the empty string. Otherwise, it will not.

To this we will add an additional type which we will call finite:

finite Each rule of is of the form $S \rightarrow w$ where $w \in \mathcal{T}^*$.

Each of these types goes by other names.

Type 0	recursively enumerable, computably enumerable
Type 1	context-sensitive
Type 2	context-free
Type 3	regular, right-linear ²
finite	finite

Table 2.1: Names for classes of formal languages.

These names refer to both the *grammars* and the *languages*. These are different kinds of objects, so it is important to know which one is being referred to in any given context.

Theorem 5 (Chomsky Hierarchy). 1. $\llbracket \text{type} - 3 \rrbracket \subseteq \llbracket \text{type} - 2 \rrbracket$ (*Scott and Rabin, 1959*).

2. $\llbracket \text{type} - 2 \rrbracket \subseteq \llbracket \text{type} - 1 \rrbracket$ (*Bar-Hillel et al., 1961*).

3. $\llbracket \text{type} - 1 \rrbracket \subseteq \llbracket \text{type} - 0 \rrbracket$ ³

For details, see, for instance, Davis and Weyuker (1983).

Exercise 9. Write rewrite grammars for as many of the languages in Example 1 as you can. Are they type 1, 2, 3 or finite grammars?

If we choose to model natural languages with formal languages, what kind of formal languages are they?

2.6 First Order and Monadic Second Order Logic

We can also define formal languages with logic, and this section explains one way to do that drawing on mathematical logic and model theory Enderton (1972, 2001); Hedman (2004); Rogers *et al.* (2013); ?.

²Technically, right-linear grammars are defined as those languages where each rule is of the form $A \rightarrow aB$ or $A \rightarrow a$ where $A, B \in \mathcal{N}$ and $a \in \mathcal{T}$. Consequently is not possible for a right linear grammar to define a language which includes the empty string.

³This is a diagonalization argument of the kind originally due to Cantor. Rogers (1967) is a good source for this kind of thing.

In what follows, we use the fact that every string $w \in \Sigma^*$ is equal to an indexed sequence of symbols, so $w = \sigma_1 \dots \sigma_n$. The positions in the string w correspond to the set of indices. It is common to call this set the *domain of w* , or *w 's domain*. So for a string of length $n \geq 1$ then its domain is the set $\{1, \dots, n\}$. If w is the empty string then its domain is empty.

We begin with First Order (FO) logic and then expand it to Monadic Second Order (MSO) logic.

2.6.1 Syntax of FO logic

We assume a countably infinite set of symbols $x, y \in V_x = \{x_0, x_1, \dots\}$ disjoint from Σ . These symbols will ultimately be interpreted as variables which range over the domains of strings, and we refer to these symbols as variables.

Definition 3 (Formulas of FO logic).

The base cases. For all variables x, y , and for all $\sigma \in \Sigma$, the following are formulas of FO logic.

- (B1) $x = y$ (*equality*)
- (B2) $x < y$ (*precedence*)
- (B3) $\sigma(x)$ (*does σ occupy position x ?*)

The inductive cases. If φ, ψ are formulas of FO logic, then so are

- (I1) $(\neg\varphi)$ (*negation*)
- (I2) $(\varphi \vee \psi)$ (*disjunction*)
- (I3) $(\varphi \wedge \psi)$ (*conjunction*)
- (I4) $(\varphi \rightarrow \psi)$ (*implication*)
- (I5) $(\varphi \leftrightarrow \psi)$ (*biconditional*)
- (I6) $(\exists x)[\varphi]$ (*existential quantification for individuals*)
- (I7) $(\forall x)[\varphi]$ (*universal quantification for individuals*)

Nothing else is a formula of FO logic.

Of course it is possible to define a FO logic with some subset of the above inductive cases and to derive the remainder. For example, negation, disjunction, and existential quantification are sufficient to derive the remainder. We include them all to facilitate writing logical formulas.

Exercise 10. Which of the following expressions are syntactically valid formulas of FO logic? Assume $\Sigma = \{a, b, c\}$.

1. $a(x)$
2. $a(x) \wedge b(y)$

3. $(a(x) \wedge b(y))$
4. $\forall x[a(x)]$
5. $(\forall x) a(x)$
6. $(\forall x) [a(x)]$
7. $(\forall x) [x = a]$
8. $(\forall x, y) [x = y]$
9. $(\forall x)[(\forall y) [x = y]]$
10. $(\forall x)[(\exists y)[y = x + 1]]$
11. $(\exists x)[(a(x) \wedge (\forall y)[(a(y) \rightarrow x = y)])]$
12. $\exists x[a(x) \wedge (\forall y)[a(y) \rightarrow x = y]]$
13. $((\exists x)[a(x)] \wedge (\forall y)[(a(y) \rightarrow x = y)])$

2.6.2 Semantics of FO logic

The *free* variables of a formula φ are those variables in φ that are not quantified. A formula is a *sentence* if *none* of its variables are free. Only sentences can be interpreted.

Exercise 11. Which of the following expressions are sentences of FO logic? Assume $\Sigma = \{a, b, c\}$.

1. $a(x)$
2. $(\forall x)[a(x)]$
3. $(\exists x)[(a(x) \wedge (\forall y)[(a(y) \rightarrow x = y)])]$
4. $((\exists x)[a(x)] \wedge (\forall y)[(a(y) \rightarrow x = y)])$

It will also be useful to think of the interpretation of a sentence φ as a function that maps strings to the set $\{\mathbf{true}, \mathbf{false}\}$. How that is done is explained below.

However, there is notation here to consider. We will write $\llbracket \varphi \rrbracket$ to denote this function. In other words, for a sentence φ of FO logic and a string w , the expression $\llbracket \varphi \rrbracket(w)$ will evaluate to true or false.

In the logical tradition, it is more common to write $w \models \varphi$, which is read as both “ w satisfies φ ” and “ w models φ ,” and which means that $\llbracket \varphi \rrbracket(w) = \mathbf{true}$. If $\llbracket \varphi \rrbracket(w)$ evaluates to false, one would write $w \not\models \varphi$. Since here I want to explain how $\llbracket \varphi \rrbracket(w)$ is calculated, I will use this notation here.

In order to evaluate $\llbracket \varphi \rrbracket(w)$, variables must be assigned values. For this reason, we will actually think of the function $\llbracket \varphi \rrbracket$ taking two arguments: one is the string w and one is the *assignment function*. The assignment function \mathbb{S} maps individual variables like x to elements of the domain (positions). You can think of it like a dictionary which maps keys (the variables) to their values (the positions). Formally, $\mathbb{S} : V_x \rightarrow D$. The assignment function \mathbb{S} may be partial, even empty. The empty assignment is denoted \mathbb{S}_0 .

We evaluate $\llbracket \varphi \rrbracket(w, \mathbb{S}_0)$. Throughout the evaluation, the assignment function \mathbb{S} gets updated. The notation $\mathbb{S}[x \mapsto e]$ updates the assignment function to add a binding of

element e to variable x . Then whether $w \models \varphi$ can be determined inductively by the below definition.

Definition 4 (Interpreting sentences of FO logic).

The base cases. For all variables x, y , for all $\sigma \in \Sigma$, and for all $w = \sigma_1 \sigma_2 \dots \sigma_n$:

$$\begin{aligned} (B1) \quad \llbracket x = y \rrbracket(w, \mathbb{S}) &\leftrightarrow \mathbb{S}(x) = \mathbb{S}(y) \\ (B2) \quad \llbracket x < y \rrbracket(w, \mathbb{S}) &\leftrightarrow \mathbb{S}(x) < \mathbb{S}(y) \\ (B3) \quad \llbracket \sigma(x) \rrbracket(w, \mathbb{S}) &\leftrightarrow \sigma_{\mathbb{S}(x)} = \sigma \end{aligned}$$

The inductive cases.

$$\begin{aligned} (I1) \quad \llbracket (\neg \varphi) \rrbracket(w, \mathbb{S}) &\leftrightarrow \neg \llbracket \varphi \rrbracket(w, \mathbb{S}) \\ (I2) \quad \llbracket (\varphi \vee \psi) \rrbracket(w, \mathbb{S}) &\leftrightarrow \llbracket \varphi \rrbracket(w, \mathbb{S}) \vee \llbracket \psi \rrbracket(w, \mathbb{S}) \\ (I3) \quad \llbracket (\varphi \wedge \psi) \rrbracket(w, \mathbb{S}) &\leftrightarrow \llbracket \varphi \rrbracket(w, \mathbb{S}) \wedge \llbracket \psi \rrbracket(w, \mathbb{S}) \\ (I4) \quad \llbracket (\varphi \rightarrow \psi) \rrbracket(w, \mathbb{S}) &\leftrightarrow \llbracket \varphi \rrbracket(w, \mathbb{S}) \rightarrow \llbracket \psi \rrbracket(w, \mathbb{S}) \\ (I5) \quad \llbracket (\varphi \leftrightarrow \psi) \rrbracket(w, \mathbb{S}) &\leftrightarrow \llbracket \varphi \rrbracket(w, \mathbb{S}) \leftrightarrow \llbracket \psi \rrbracket(w, \mathbb{S}) \\ (I6) \quad \llbracket (\exists x)[\varphi] \rrbracket(w, \mathbb{S}) &\leftrightarrow (\bigvee_{e \in D} \llbracket \varphi \rrbracket(w, \mathbb{S}[x \mapsto e])) \\ (I7) \quad \llbracket (\forall x)[\varphi] \rrbracket(w, \mathbb{S}) &\leftrightarrow (\bigwedge_{e \in D} \llbracket \varphi \rrbracket(w, \mathbb{S}[x \mapsto e])) \end{aligned}$$

The formal language that a sentence φ denotes is given by

$$\llbracket \varphi \rrbracket = \{w \in \Sigma^* : w \models \varphi\},$$

i.e. all and only those strings w such that $\llbracket \varphi \rrbracket(w, \mathbb{S}_0) = \mathbf{true}$.

Exercise 12. Determine the formal languages of the following logical sentences.

1. $(\forall x)[a(x)]$
2. $(\exists x)[a(x)]$
3. $(\exists x)[(a(x) \wedge (\forall y)[(a(y) \rightarrow x = y)])]$
4. $(\exists x)[(\exists y)[((a(x) \wedge a(y) \wedge x < y))]]$

Exercise 13.

1. Write FO sentences for the following languages.

- (a) All words which begin with a (so $a\Sigma^*$)
- (b) All words which end with a (so Σ^*a)

2. Write FO sentences for as many of the formal languages in Example 1 as you can.

Hint: it will be useful to define logical predicates for the successor relation, and the tier successor relation and to use those.

Next we turn to Monadic Second Order (MSO) logic.

2.6.3 Syntax of MSO logic

Every formula of FO logic is a formula of MSO logic. MSO logic extends FO logic as follows.

In addition to the countably infinite set of symbols $V_x = \{x_0, x_1, \dots\}$, we assume another countably infinite set of symbols $V_X = \{X_0, X_1, \dots\}$, disjoint from Σ . These symbols will ultimately be interpreted as variables which range over *subsets* of the domains of strings. We refer to the symbols of V_x as set variables and the elements of V_x as individual variables.

Definition 5 (Formulas of MSO logic).

The base cases. *The base cases are the same as FO logic along with*

$$(B_4) \quad x \in X \quad (\textit{membership})$$

The inductive cases. *If φ, ψ are formulas of FO logic, then so are*

$$\begin{aligned} (I_8) \quad (\exists X)[\varphi] & \quad (\textit{existential quantification for sets}) \\ (I_9) \quad (\forall X)[\varphi] & \quad (\textit{universal quantification for sets}) \end{aligned}$$

Nothing else is a formula of FO logic.

2.6.4 Semantics of MSO logic

Recall the assignment function \mathbb{S} we used to interpret sentences of FO logic. We also use \mathbb{S} to keep track of the assignments of set variables, and the notation $\mathbb{S}[X \mapsto S]$ updates the assignment function to add a binding of the set of elements S to variable X .

With that in mind, the interpretation of sentences of MSO logic is the same as FO logic along with the following.

Definition 6 (Interpreting sentences of MSO logic).

The base cases.

$$(B_4) \quad \llbracket x \in X \rrbracket(w, \mathbb{S}) \leftrightarrow \mathbb{S}(x) \in \mathbb{S}(X)$$

The inductive cases.

$$\begin{aligned} (I8) \quad \llbracket (\exists X)[\varphi] \rrbracket(w, \mathbb{S}) &\leftrightarrow (\bigvee_{S \subseteq D} \llbracket \varphi \rrbracket(w, \mathbb{S}[X \mapsto S])) \\ (I9) \quad \llbracket (\forall X)[\varphi] \rrbracket(w, \mathbb{S}) &\leftrightarrow (\bigwedge_{S \subseteq D} \llbracket \varphi \rrbracket(w, \mathbb{S}[X \mapsto S])) \end{aligned}$$

That's it!

Exercise 14. 1. What language does the following MSO expression describe?

$$\begin{aligned} &(\exists X)[(\exists Y)[\\ &\quad (\forall x)[(\forall y)[\\ &\quad \quad (((\\ &\quad \quad \quad (x \in X \leftrightarrow (\neg x \in Y)) \\ &\quad \quad \quad \wedge (\mathbf{first}(x) \rightarrow x \in X)) \\ &\quad \quad \quad \wedge (\mathbf{last}(x) \rightarrow x \in Y)) \\ &\quad \quad \quad \wedge ((x \triangleleft y \wedge x \in X) \rightarrow y \in Y)) \\ &\quad \quad \quad \wedge ((y \triangleleft x \wedge y \in Y) \rightarrow x \in X)) \\ &\quad \quad]]] \end{aligned}$$

(Make sure **first** and **last** are defined appropriately.)

2. Write a MSO sentence which denotes the language whose strings are all and only those with an even number of a symbols. Assume $\Sigma = \{a, b\}$.

2.6.5 Theorems

Let $\llbracket MSO \rrbracket$ denote the class of formal languages definable with sentences of MSO logic and $\llbracket FO \rrbracket$ denote the class of formal languages definable with sentences of FO logic.

Theorem 6 (Büchi, Elgot, and Trakhtenbrot). $\llbracket MSO \rrbracket = \llbracket RE \rrbracket$.

Theorem 7 (Schützenberger). $\llbracket FO \rrbracket = \llbracket SFE \rrbracket$.

Consequently, it follows that $\llbracket FO \rrbracket \subsetneq \llbracket MSO \rrbracket$.

2.6.6 Other Logics

In the logical languages defined above, we used the precedence ($<$) as a primitive formula. So the MSO and FO languages defined above are often referred to as $MSO(<)$ and $FO(<)$.

What if we replace precedence with successor (\triangleleft) so that $\llbracket x \triangleleft y \rrbracket$ is true iff $y = x + 1$ (so y is the next position after x).

Theorem 8 (Thomas 1982). $\llbracket FO(\triangleleft) \rrbracket \subsetneq \llbracket FO(<) \rrbracket$.

This is because successor is definable from precedence with first order logic but precedence is not first-order definable with successor.

However, precedence is MSO-definable with successor. Consequently we have the following hierarchy.

$$\llbracket FO(\triangleleft) \rrbracket \subsetneq \llbracket F(<) \rrbracket \subsetneq \llbracket MSO(\triangleleft) \rrbracket = \llbracket MSO(<) \rrbracket$$

There are many other kinds of logical languages, including quantifier free logic, modal logic, and Boolean Recursive Monadic Schemes.

Chapter 3

Strings and Trees

In this chapter, we define strings and trees of finite size inductively.

3.1 Strings

Informally, strings are sequences of symbols.

What are symbols? It is standard to assume a set of symbols called the *alphabet*. The Greek symbol Σ is often used to represent the alphabet but people also use S , A , or anything else. The symbols can be anything: IPA letters, morphemes, words, part-of-speech categories. Σ can be infinite in size, but we will usually consider it to be finite.

There are different ways strings can be defined formally. Here we define them as a recursive data structure. They are defined inductively with a constructor (\cdot) , the alphabet *Sigma* and the base case λ . What is λ ? It is the empty string. It is usually written with one of the Greek letters ϵ or λ . It's just a matter of personal preference. The empty string is useful from a mathematical perspective in the same way the number zero is useful. Zero is a special number because for all numbers x it is the case that $0 + x = x + 0 = x$. The empty string serves the same special purpose. It is the unique string with the following special property with respect to concatenation (denoted \circ).¹

$$\text{For all strings } w, \lambda \circ w = w \circ \lambda = w \quad (3.1)$$

Definition 7 (Strings).

Base Case: λ is a string.

Inductive Case: If $a \in \Sigma$ and w is a string then $a \cdot (w)$ is a string.

Example 5. Let $\Sigma = \{a, b, c\}$. Then the following are strings.

1. $a \cdot (b \cdot (c \cdot (\lambda)))$

¹Concatenation will be defined in an exercise below. Our goal would be to ensure the property mentioned holds once concatenation is defined between strings.

2. $a \cdot (a \cdot (a \cdot (\lambda)))$
3. $a \cdot (b \cdot (c \cdot (c \cdot (\lambda))))$

Frankly, writing all the parentheses and “ \cdot ” is cumbersome. So the above examples are much more readable if written as follows.

1. abc
2. aaa
3. $abcc$

Technically, when we write the string abc , we literally mean the following structure: $a \cdot (b \cdot (c \cdot (\lambda)))$.

The above definition provides a unique “derivation” for each string.

Example 6. Let $\Sigma = \{a, b, c\}$. We claim $w = a \cdot (b \cdot (a \cdot (\lambda)))$ is a string. There is basically one way to show this. First we observe that $a \in \Sigma$ so whether w is a string depends, by the inductive case, on whether $x = b \cdot (a \cdot (\lambda))$ is a string. Next we observe that since $b \in \Sigma$ whether x is a string depends on whether $y = a \cdot (\lambda)$ is a string, again by the inductive case. Once more, since $a \in \Sigma$ whether y is a string depends on whether λ is a string. Finally, by the base case λ is a string and so the dominoes fall: y is a string so x is a string and so w is a string.

This unique derivability is useful in many ways. For instance, suppose we want to determine the length of a string. Here is how we can do it.

Definition 8 (string length). *The length of a string w , written $|w|$, is defined as follows. If $w = \lambda$ then $|w| = 0$. If not, then $w = a \cdot (x)$ where x is some string and $a \in \Sigma$. In this case, $|w| = |x| + 1$.*

Note length is an inductive definition!

Example 7. What is the length of string $w = abcc$? Well, as before we see that $w = a \cdot x$ where $x = bcc$. Thus, $|w| = 1 + |bcc|$. What is the length of bcc ? Well, $x = b \cdot y$ where $y = cc$. So now we have $|w| = 1 + (1 + |cc|)$. Since $y = c \cdot z$ where $z = c$ we have $|w| = 1 + (1 + (1 + |c|))$. Since c is the structure $c(\lambda)$, its length will be $1 + |\lambda|$. Finally, by the *base case* we have $|w| = 1 + (1 + (1 + (1 + (0)))) = 4$.

It’s interesting to observe how the structure of the computation of length is the *same* structure as the object itself.

$$\begin{array}{ccccccc} a & \cdot & (& b & \cdot & (& c & \cdot & (& c & \cdot & (& \lambda &) &) &) &) \\ 1 & + & (& 1 & + & (& 1 & + & (& 1 & + & (& 0 &) &) &) &) \end{array}$$

We can now define concatenation between strings. First we define ReverseAppend, which takes two strings as arguments and returns a third string.

Definition 9 (reverse append). Reverse append is a binary operation over strings, which we denote \otimes_{revapp} . You can also think of it as a function which takes two strings w_1 and w_2 as arguments and returns another string. Here is the base case. If $w_1 = \lambda$ then it returns w_2 . So we can write $\lambda \otimes_{\text{revapp}} w = w$. Otherwise, there is $a \in \Sigma$ such that $w_1 = a \cdot (x)$ for some string x . In this case, reverse append returns $x \otimes_{\text{revapp}} a \cdot (w_2)$.

Exercise 15. Work out what $abc \otimes_{\text{revapp}} def$ equals.

Exercise 16. What is $abc \otimes_{\text{revapp}} \lambda$? Write a definition for string reversal.

Exercise 17. Define the concatenation of two strings w_1 and w_2 using reverse append and string reversal. Prove this definition satisfies Equation 3.1.

The set of all strings of finite length from some alphabet Σ , including the empty string, is written Σ^* . A *stringset* is a subset of Σ^* .

Stringsets are often called *formal languages*. From a linguistic perspective, it is the study of string well-formedness.

3.2 Trees

Trees are like strings in that they are recursive structures. Informally, trees are structures with a single ‘root’ node which dominates a sequence of trees.

Formally, trees extend the dimensionality of string structures from 1 to 2. In addition to linear order, the new dimension is dominance.

Unlike strings, we will not posit “empty” trees because every tree has a root.

Like strings, we assume a set of symbols Σ . This is sometimes partitioned into symbols of different types depending on whether the symbols can only occur at the leaves of the trees or whether they can dominate other trees. We don’t make such a distinction here.

Definition 10 (Trees). If $a \in \Sigma$ and w is a string of trees then $a[w]$ is a tree.

A tree $a[\lambda]$ is called a *leaf*. Note if $w = \lambda$ we typically write $a[]$ instead of $a[\lambda]$. Similarly, if $w = t_1 \cdot (t_2 \cdot (\dots (t_n \cdot (\lambda)) \dots))$, we write $a[t_1 t_2 \dots t_n]$ for readability.

The definition of trees above may appear circular. It appears circular since it defines trees in terms of strings of trees. However, this circularity is an illusion. The definition has a solid recursive base case, as I will now explain. The key to resolving this illusion is to construct the full set of trees in steps. For example, λ is a string (of trees) by the definition of string. With the empty string λ and the finite alphabet Σ we can define a set of trees $T_0 = \{a[\lambda] \mid a \in \Sigma\}$. T_0 is the set of all logically possible leaves (trees of depth 0). T_0 is a finite alphabet and so T_0^* is a well defined set of strings over this alphabet. For example $w = a[] \cdot (b[] \cdot (c[] \cdot (b[] \cdot (\lambda))))$ is a string of trees.

So far, with Σ and λ we built T_0 . The definition of strings gives us T_0^* . Now with Σ and T_0^* we can build $T_1 = \{a[w] \mid a \in \Sigma, w \in T_0^*\} \cup T_0$. T_1 includes T_0 in addition to all trees

of depth 1. With T_1 , and the definition of strings we have T_1^* . Now with Σ and T_1^* we can build $T_2 = \{a[w] \mid a \in \Sigma, w \in T_1^*\} \cup T_1$.

More generally, we define $T_{n+1} = \{a[w] \mid a \in \Sigma, w \in T_n^*\} \cup T_n$. Finally, let the set of all logically possible trees be denoted with $\Sigma^T = \bigcup_{i \in \mathbb{N}} T_i$. Figure 3.1 illustrates this construction.

Figure 3.1: The inductive definition of trees.

Here are some examples of trees.

Example 8. Let $\Sigma = \{\text{NP}, \text{VP}, \text{S}\}$. Then the following are trees.

1. $\text{S}[\text{NP}[] \text{VP}[\text{VP}[] \text{NP}[]]]$
2. $\text{NP}[\text{VP}[] \text{S}[] \text{S}[] \text{VP}[]]$
3. $\text{NP}[\text{NP}[\text{NP}[] \text{VP}[] \text{S}[]]]$

We might draw these structures as follows.

Regarding the tree in (1), its leaves are NP, VP, and NP.

As before, we can now write definitions to get information about trees. For instance here is a definition which gives us the number of nodes in the tree.

Definition 11. The size of a tree t , written $|t|$, is defined as follows. If there is some $a \in \Sigma$ such that $t = a[]$ then its size is 1. If not, then $t = a[t_1 t_2 \dots t_n]$ where $a \in \Sigma$ and each t_i is a tree. Then $|t| = 1 + |t_1| + |t_2| + \dots + |t_n|$.

Exercise 18. Using the above definition, calculate the size of the trees (1)-(3) above. Write out the calculation explicitly.

Here is a definition for the *width* of a tree.

Definition 12. The depth of a tree t , written $\mathbf{depth}(t)$, is defined as follows. If there is some $a \in \Sigma$ such that $t = a[]$ then its depth is 0. If not, then $t = a[t_1 t_2 \dots t_n]$ where $a \in \Sigma$ and each t_i is a tree. Then $\mathbf{depth}(t) = 1 + \max\{\mathbf{depth}(t_1), \mathbf{depth}(t_2), \dots, \mathbf{depth}(t_n)\}$ where \max takes the largest number in the set.

Definition 13. The width of a tree t , written $\mathbf{width}(t)$, is defined as follows. If there is some $a \in \Sigma$ such that $t = a[]$ then its width is 0. If not, then $t = a[t_1 t_2 \dots t_n]$ where $a \in \Sigma$ and each t_i is a tree. Then $\mathbf{width}(t) = \max\{n, \mathbf{width}(t_1), \mathbf{width}(t_2), \dots, \mathbf{width}(t_n)\}$ where \max takes the largest number in the set.

The set of trees Σ^T contains all trees of arbitrary width. Much research also effectively concerns the set of all and only those trees whose width is bounded by some number n . Let $\Sigma^{T(n)} = \{t \in \Sigma^T \mid \mathbf{width}(t) \leq n\}$.

Exercise 19. The *yield* of a tree t , written $\mathbf{yield}(t)$, maps a tree to a string of its leaves. For example let t be the tree in (1) in Example 8 above. Then its yield is the string “NP VP NP”.

3.2.1 String Exercises

Exercise 20. Let Σ be the set of natural numbers. So we are considering strings of numbers.

1. Write the definition of the function *addOne* which adds one to each number in the string. So *addOne* would change the string $5 \cdot (11 \cdot (4 \cdot (\lambda)))$ to $6 \cdot (12 \cdot (5 \cdot (\lambda)))$. Using this definition, show *addOne* of the following number strings is calculated.

- (a) $11 \cdot (4 \cdot (\lambda))$
- (b) $3 \cdot (2 \cdot (\lambda))$
- (c) λ

2. Write the definition of the *timesTwo* of the numbers in the string. So *timesTwo* would change the string $5 \cdot (11 \cdot (4 \cdot (\lambda)))$ to $10 \cdot (22 \cdot (8 \cdot (\lambda)))$. Using this definition, show *timesTwo* of the following number strings is calculated.

- (a) $11 \cdot (4 \cdot (\lambda))$
- (b) $3 \cdot (2 \cdot (\lambda))$
- (c) λ

Exercise 21. Let Σ be the set of natural numbers. So we are considering strings of numbers.

1. Write the definition of the *sum* of the numbers in the string. Using this definition, show how the sum of the following number strings is calculated.

- (a) $11 \cdot (4 \cdot (\lambda))$

- (b) $3 \cdot (2 \cdot (\lambda))$
 - (c) λ
2. Write the definition of the *product* of the numbers in the string. Using this definition, show how the sum of the following number strings is calculated.
- (a) $11 \cdot (4 \cdot (\lambda))$
 - (b) $3 \cdot (2 \cdot (\lambda))$
 - (c) λ

3.2.2 Tree Exercises

Exercise 22. Let Σ be the set of natural numbers. Now let's consider trees of numbers.

1. Write the definition of the function *addOne* which adds one to each number in the tree. Using this definition, calculate *addOne* as applied to the trees below.
 - (a) $4[12[]3[]]$
 - (b) $4[12[]3[1[]2[]]]$
 - (c) $4[12[7[]7[6[]]]3[1[]2[]]]$
2. Write the definition of the function *isLeaf* which changes the nodes of a tree to **True** if it is a leaf node or to **False** if it is not. Using this definition, calculate *isLeaf* as applied to the trees below.
 - (a) $4[12[]3[]]$
 - (b) $4[12[]3[1[]2[]]]$
 - (c) $4[12[7[]7[6[]]]3[1[]2[]]]$

Exercise 23. Let Σ be the set of natural numbers. Now let's consider trees of numbers.

1. Write the definition of the *sum* of the numbers in the tree. Using this definition, show how the sum of the following number trees is calculated.
 - (a) $4[12[]3[]]$
 - (b) $4[12[]3[1[]2[]]]$
 - (c) $4[12[7[]7[6[]]]3[1[]2[]]]$
2. Write the definition of the *yield* of the numbers in the string. The yield is a string with only the leaves of the tree in it. Using this definition, calculate the yields of the trees below.
 - (a) $4[12[]3[]]$
 - (b) $4[12[]3[1[]2[]]]$
 - (c) $4[12[7[]7[6[]]]3[1[]2[]]]$

Chapter 4

String Acceptors

4.1 Deterministic Finite-state String Acceptors

4.1.1 Orientation

This section is about deterministic finite-state acceptors for strings. The term *finite-state* means that the memory is bounded by a constant, no matter the size of the input to the machine. The term *deterministic* means there is single course of action the machine follows to compute the output from some input. This is in contrast to *non-deterministic machines* which can be thought of as pursuing multiple computations simultaneously. The term *acceptor* is synonymous with *recognizer*. It means that this machine solves *membership problems*: given a set of objects X and input object x , does x belong to X ? The term *string* means we are considering the membership problem over stringsets. So X is a set of strings (so $X \subseteq \Sigma^*$) and the input x is a string.

4.1.2 Definitions

Definition 14. A deterministic finite-state acceptor (DFA) is a tuple $(Q, \Sigma, q_0, F, \delta)$ where

- Q is a finite set of states;
- Σ is a finite set of symbols (the alphabet);
- $q_0 \in Q$ is the initial state;
- $F \subseteq Q$ is a set of accepting (final) states; and
- δ is a function with domain $Q \times \Sigma$ and co-domain Q . It is called the transition function.

We extend the domain of the transition function to $Q \times \Sigma^*$ as follows. In these notes, the empty string is denoted with λ .

$$\begin{aligned}\delta^*(q, \lambda) &= q \\ \delta^*(q, aw) &= \delta^*(\delta(q, a), w)\end{aligned}\tag{4.1}$$

Consider some DFA $A = (Q, \Sigma, q_0, F, \delta)$ and string $w \in \Sigma^*$. If $\delta^*(q_0, w) \in F$ then we say A *accepts/recognizes/generates* w . Otherwise A *rejects* w .

Definition 15. The stringset recognized by A is $L(A) = \{w \in \Sigma^* \mid \delta^*(q_0, w) \in F\}$.

4.1.3 Exercises

Exercise 24. This exercise is about designing DFA. Let $\Sigma = \{a, b, c\}$. Write DFA which express the following generalizations on word well-formedness.

1. All words begin with a consonant, end with a vowel, and alternate consonants and vowels.
2. Words do not contain *aaa* as a substring.
3. If a word begins with *a*, it must end with *c*.
4. Words must contain two *bs*.
5. All words have an even number of vowels.

Exercise 25. This exercise is about reading and interpreting DFA. Provide generalizations in English prose which accurately describe the stringset these DFA describe.

4. Write the DFA in #1-3 in mathematical notation. So what is Q, Σ, q_0, F , and δ ?

4.2 Properties of DFA

Note that for a DFA A , its transition function δ may be partial. That is, there may be some $q \in Q, a \in \Sigma$ such that $\delta(q, a)$ is undefined. If δ is a partial function, δ^* will be also. It is assumed that if $\delta^*(q_0, w)$ is undefined, then A rejects w .

We can always make δ total by adding one more state to Q . To see how, call this new state \diamond . Then for each $(q, a) \in Q \times \Sigma$ such that $\delta(q, a)$ is undefined, define $\delta(q, a)$ to equal \diamond . Every string which was formerly undefined w.r.t. to δ^* is now mapped to \diamond , a non-accepting state. This state is sometimes called the *sink* state or the *dead* state.

Definition 16. A DFA is complete if δ is a total function. Otherwise it is incomplete.

It is possible to write DFA which have many useless states. A state can be useless in two ways. First, there may be no string which forces the machine to transition into the state. Second, there may be a state from which no string

Definition 17. A state q in a DFA A is useful if there is a string w such that $\delta^*(q_0, w) = q$ and a string v such that $\delta^*(q, v) \in F$. Otherwise q is useless. If every state in A is useful, then A is called trim.

Not all complete DFAs are trim. If there is a sink state, it is useless in the above sense of the word.

Definition 18. A DFA A is minimal if there is no other DFA A' such that $L(A) = L(A')$ and A' has fewer states than A .

Technically, not all complete DFAs are minimal. If there is a sink state, it is not minimal.

Exercise 26. Consider the DFAs in the exercise 25. Are they complete? Trim? Minimal?

4.3 Some Closure Properties of Regular Languages

A set of objects X is *closed* under an operation \circ if for all objects $x, y \in X$ it is the case that $x \circ y \in X$ too.

We can easily show that the union of any two regular stringsets R and S is also regular. Let $A_R = (Q_R, \Sigma, q_{0R}, F_R, \delta_R)$ be the DFA recognizing R and let $A_S = (Q_S, \Sigma, q_{0S}, F_S, \delta_S)$ be the DFA recognizing S . We can assume A_R and A_S are complete. We assume the same alphabet.

Construct $A = (Q, \Sigma, q_0, F, \delta)$ as follows.

- $Q = Q_R \times Q_S$.
- $q_0 = (q_{0R}, q_{0S})$.
- $F = \{(q_r, q_s) \mid q_r \in F_R \text{ or } q_s \in F_S\}$.
- $\delta((q_r, q_s), a) = (q'_r, q'_s)$ where $\delta_R(q_r, a) = q'_r$ and $\delta_S(q_s, a) = q'_s$.

Theorem 9. $L(A) = R \cup S$.

Similarly, the same kind of construction shows that the intersection of any two regular stringsets is regular. Construct $B = (Q, \Sigma, q_0, F, \delta)$ as follows.

- $Q = Q_R \times Q_S$.
- $q_0 = (q_{0R}, q_{0S})$.
- $F = \{(q_r, q_s) \mid q_r \in F_R \text{ and } q_s \in F_S\}$.
- $\delta((q_r, q_s), a) = (q'_r, q'_s)$ where $\delta_R(q_r, a) = q'_r$ and $\delta_S(q_s, a) = q'_s$.

Theorem 10. $L(B) = R \cap S$.

Here are some additional questions we are interested in for regular stringsets R and S .

1. Is the complement of R (denoted \overline{R}) a regular stringset?
2. Is $R \setminus S$ a regular stringset?
3. Can we decide whether $R \subseteq S$?
4. Is $R \circ S$ a regular stringset? (Note $R \circ S = \{rs \mid r \in R \text{ and } s \in S\}$)
5. Is R^* a regular stringset? (Note $R^0 = \{\lambda\}$, $R^n = R^{n-1}R$, $R^* = \bigcup_{n \in \mathbb{N}^0} R^n$)

The answers to all of these questions is Yes. With a little thought about complete DFA, the answers to first three follow very easily.

Theorem 11. *If R is a regular stringset then the complement of R is regular.*

Proof (Sketch). If R is a regular stringset then there is a complete DFA $A = (Q, \Sigma, q_0, F, \delta)$ which recognizes it. Let $B = (Q, \Sigma, q_0, F', \delta)$ where $F' = Q \setminus F$. We claim $L(B) = \overline{R}$. \square

Corollary 1. *If R, S are regular stringsets then so is $R \setminus S$ since $R \setminus S = R \cap \overline{S}$.*

Corollary 2. *If R, S are regular stringsets then it is decidable whether $R \subseteq S$ since $R \subseteq S$ iff $R \setminus S = \emptyset$.*

Corollary 3. *If R, S are regular stringsets then it is decidable if $R = S$ since $R = S$ iff $R \subseteq S$ and $S \subseteq R$.*

We postpone explaining how and why for the last two questions.

4.4 Non-deterministic Finite-state String Acceptors

4.4.1 Orientation

This section is about non-deterministic finite-state acceptors for strings. The term *finite-state* means that the memory is bounded by a constant, no matter the size of the input to the machine. The term *non-deterministic* means there are potentially many computational paths the machine may follow to compute the output from some input string. As we will see later, *deterministic machines* pursue at most a single computation. The term *acceptor* is synonymous with *recognizer*. It means that this machine solves *membership problems*: given a set of objects X and input object x , does x belong to X ? The term *string* means we are considering the membership problem over stringsets. So X is a set of strings (so $X \subseteq \Sigma^*$) and the input x is a string.

4.4.2 Non-deterministic string acceptors

Definition 19. A non-deterministic finite-state acceptor (NFA) is a tuple $(Q, \Sigma, I, F, \delta)$ where

- Q is a finite set of states;
- Σ is a finite set of symbols (the alphabet);
- $I \subseteq Q$ is a set of initial (start) states;
- $F \subseteq Q$ is a set of accepting (final) states; and
- $\delta \subseteq Q \times \Sigma \cup \{\epsilon\} \times Q$ is the transition relation.

The symbol ϵ denotes a “free” change of state; that is the state of the system can change without any input being consumed.

There are a couple ways to think about the transition function. One way is to think that when processing a string, there are multiple paths to take. For example, consider the machine below which recognizes the set of strings where every non-empty string must end in a consonant. Given the input string bb , when the first b is read and the machine is in state 0,

Figure 4.1: An example NFA.

it could transition to state 1 or 2. In fact, the epsilon transition from state 0 means that the machine could transition to state 1 without even reading the first symbol of the string. If

we think of the machine as occupying a single state at any given moment, there are multiple paths that need to be explored. As long as at least one of them leads from a start state to a final state when reading the whole string, we can say the machine accepts the string. Under this way of thinking, there are potentially many paths that need to be explored and tracked until a successful one is found.

The other way to think about is to think of the machine being in several states simultaneously. In the example above, when the first b is read, we can think of the machine as transitioning from state 0 to both states 1 and 2. In other words, it originally was in state 0 and after reading the b , it is in “state” $\{1, 2\}$. In fact, because of the epsilon transition from state 0, before the first b is read, the machine can be said to be in both states 0 and 2. It is this way of thinking that we use to define the set of strings that NFA recognize, and it also is the intuition behind the fact that stringsets recognizable by non-deterministic finite-state acceptors are the same as those recognizable by DFAs. We will use this same insight to define how to decide whether NFA recognizes an input string or not.

The *epsilon closure* of a set of states $S \subseteq Q$ is the smallest subset S' of Q satisfying these properties:

1. $S \subseteq S'$
2. For all $q, r \in Q$: if $q \in S'$ and $r \in \delta(q, \epsilon)$ then $r \in S'$.

The epsilon closure of Q is denoted $C_\epsilon(Q)$.

δ is a relation and in order to define a “process” function, we use δ to define related functions. First, we define $\delta' : Q \times \Sigma \rightarrow \wp(Q)$. Recall that for any set A , $\wp(A)$ denotes the powerset of A , which is the set of all subsets of A .

$$\delta'(q, a) = \{q' \mid (q, a, q') \in \delta\}$$

Next we define $\delta'' : \wp(Q) \times \Sigma \rightarrow \wp(Q)$ as follows.

$$\delta''(Q, a) = \bigcup_{q \in Q} \delta'(q, a)$$

Finally, we can explain how a NFA processes strings using the recursive definition below.

$$\begin{aligned} \pi(Q, \lambda) &= Q \\ \pi(Q, aw) &= \pi(C_\epsilon(\delta''(Q, a)), w) \end{aligned} \tag{4.2}$$

Consider some NFA $A = (Q, \Sigma, I, F, \delta)$ and string $w \in \Sigma^*$. If $\pi(C_\epsilon(I), w) \cap F \neq \emptyset$ then we say A *accepts/recognizes/generates* w . Otherwise A *rejects* w .

Definition 20. *The stringset recognized by A is $L(A) = \{w \in \Sigma^* \mid \pi(C_\epsilon(I), w) \cap F \neq \emptyset\}$.*

Exercise 27.

1. Non-determinism makes expressing some stringsets easier because it can be done with fewer states.

- (a) Write an acceptor for the set of strings where the second-to-last letter must be a consonant.
 - (b) Write an acceptor for the set of strings where the third-to-last letter must be a consonant.
2. Use the plurality of initial states to show that if R and S are stringsets each recognized by some NFA that the union $R \cup S$ is also recognized by a NFA.
 3. Use epsilon transitions to show that if R and S are stringsets each recognized by some NFA that the concatenation RS is also recognized by a NFA.

4.4.3 Closure under concatenation, union, Kleene Star

Theorem 12. $\llbracket NFA \rrbracket = \llbracket RE \rrbracket$

It is easy to prove that $\llbracket RE \rrbracket \subseteq \llbracket NFA \rrbracket$. Recall how the REs were defined with base cases and inductive cases.

Exercise 28. Write a NFA which recognizes the same language as each of the RE base cases.

We want to show the following.

1. Given NFA A, B , that there exists a NFA recognizing the $L(A) \circ L(B)$ (closure under concatenation).
2. Given NFA A, B , that there exists a NFA recognizing the $L(A) \cup L(B)$ (closure under union).
3. Given NFA A , that there exists a NFA recognizing the $(L(A))^*$ (closure under Kleene star).

The existence of epsilon transitions make this this easy to show.

1. For closure under concatenation, the NFA recognizing $L(A) \circ L(B)$ is

- $Q = Q_A \cup Q_B$
- $\Sigma = \Sigma_A \cup \Sigma_B$
- $I = I_A$
- $F = F_B$
- $\delta = \delta_A \cup \delta_B \cup \{(q, \epsilon, r) : q \in F_A, r \in I_B\}$

2. For closure under union, the NFA recognizing $L(A) \cup L(B)$ is

- $Q = Q_A \cup Q_B$

- $\Sigma = \Sigma_A \cup \Sigma_B$
- $I = I_A \cup I_B$
- $F = F_B \cup F_B$
- $\delta = \delta_A \cup \delta_B$

3. For closure under Kleene star, the NFA recognizing the $(L(A))^*$.

- $Q = Q_A \cup \{\heartsuit, \spadesuit\}$
- $\Sigma = \Sigma_A$
- $I = \{\heartsuit\}$
- $F = \{\spadesuit\}$
- $\delta = \delta_A \cup \{(\heartsuit, \epsilon, q) : q \in I_A\} \cup \{(q, \epsilon, \spadesuit) : q \in F_A\} \cup \{(\heartsuit, \epsilon, \spadesuit), (\spadesuit, \epsilon, \heartsuit)\}$

We can visualize the argument as follows. Figure 4.2 visualizes two NFA, A and B . Schematically, the initial states are on the left and the final states are on the right. The construction

Figure 4.2: Two finite state machines with a set of initial states (leftside) and a set of final states (rightside).

for concatenation is illustrated in Figure 4.3. The construction for union is illustrated in

Figure 4.3: Concatenation of two NFAs.

Figure 4.4. The construction for Kleene star is illustrated in Figure 4.5.

Proving that there is a RE for any NFA is only a little more complicated. It is reviewed in several textbooks such as Sipser (1997) and Hopcroft *et al.* (2001) and we will not review it here.

Since NFA recognize the same languages as REs, we will call this class of languages *regular languages*. Next we turn to DFA.

Figure 4.4: Union of two NFAs.

Figure 4.5: Kleene Star of one NFA.

4.5 Determinizing NFA

In this section, we prove the following theorem.

Theorem 13. $\llbracket NFA \rrbracket = \llbracket DFA \rrbracket$.

Since every DFA is a NFA, it follows that any language recognized by a DFA is also recognized by some NFA. It remains to be shown that for any language recognized by a NFA, there is a DFA that recognizes the same language.

The key idea is one encountered earlier: when processing a string in a NFA, instead of pursuing multiple paths of single states, we can pursue a single path of multiple states. Since there are finitely many states Q in a NFA, the number of sets of multiple states is also finite, and is bounded by the powerset of Q . Thus for any NFA $A = (Q_A, \Sigma_A, I_A, F_A, \delta_A)$, we can construct a DFA $B = (Q, \Sigma, I, F, \delta)$ using *the powerset construction* shown below.

- $Q = \wp(Q_A)$ is a finite set of states;
- $\Sigma = \Sigma_A$ is a finite set of symbols (*the alphabet*);
- I_A is the *initial* state;
- $q \in Q$ is a set of *accepting* state iff $q \cap F_A \neq \emptyset$
- $\delta(q, a) = r$ iff $C_\epsilon(\delta''_A(C_\epsilon(q), a)) = r$.

Then one can prove $L(A) = L(B)$, and it follows that $\llbracket NFA \rrbracket = \llbracket DFA \rrbracket$.

Algorithms which determinize non-deterministic finite-state machines do not build the entire powerset. Instead they proceed incrementally beginning with the start state I_A and proceeding through the alphabet. New states are added as they are needed.

Exercise 29. Determinize the NFA in Figure 4.1.

4.6 Minimizing DFA

Here we show that for each regular stringset R , there is a smallest DFA which recognizes R . This DFA is unique (discounting the names of the states).

Consider any DFA A . The idea is that some states are doing the “same work” as other states. Such states are said to be *indistinguishable*. States that are indistinguishable from each other are grouped into blocks. These blocks become the states of the minimal DFA which recognizes the same stringset as A .

Given a DFA A recognizing a stringset R , to find the minimal DFA recognizing R we must do the following:

1. Determine which states of A are indistinguishable.
2. Using this information, construct the minimal DFA.

4.6.1 Identifying indistinguishable states

Consider $A = (Q, \Sigma, i, F, \delta)$. Two states q, r are *distinguishable* in A if there is some string w such that $\delta^*(q, w) \in F$ and $\delta^*(r, w) \notin F$. In other words, if there is a string that causes A to transition from state q to an accepting state but would cause A to transition from state r to a rejecting state then q and r are distinguishable. We say w *distinguishes* q from r .

We can determine whether a distinguishing string w exists for q and r recursively. There are two key observations to see why. First, observe that the empty string λ distinguishes accepting states from rejecting states. Second, if w distinguishes q from r and string u causes A to transition from state q' to q and causes A to transition from state r' to r then it is the case that string uw distinguishes q' from r' . Formally:

Base case: (q, r) is distinguishable if $q \in F$ and $r \notin F$.

Inductive Step: (q', r') is distinguishable if (q, r) is distinguishable and there is $a \in \Sigma$ such that $\delta(q', a) = q$ and $\delta(r', a) = r$.

It is sufficient to check individual symbols in Σ in the inductive step and repeat it until no new distinguishable states are found.

To see why, consider the following. The first iteration checks to see if any 1-long strings distinguish states in A . The second iteration checks to see if any 2-long strings distinguish states in A . Generally, the k th iteration checks to see if any k -long strings distinguish states in A . Importantly, if there is a string w of length k distinguishing q from r in A then there must be a string v of length $k - 1$ and a symbol $a \in \Sigma$ distinguishing $q' = \delta(q, a)$ from $r' = \delta(r, a)$ in A . This justifies why the inductive step can stop iterating if no new distinguishable states are found on the present iteration. It is not possible to find a k -long string distinguishing states if no $(k - 1)$ -long string distinguishes any states.

At the end of this process we have a set of distinguishable state-pairs. The state-pairs in A that are not distinguishable are *indistinguishable*.

4.6.2 Building the minimal DFA

Once the indistinguishable states have been identified, a new DFA can be constructed. The indistinguishable state-pairs of A partition its states into *blocks*. A block is just a set of states. States q and r are in the same block only if (q, r) is an indistinguishable state-pair.

The process by which distinguishable states are found ensures that the set of indistinguishable state-pairs is closed under transitivity. In other words, if (q, r) and (r, s) are indistinguishable state-pairs then so is (q, s) . More generally, the *indistinguishable relation* is an equivalence relation satisfying not only transitivity but also reflexivity and symmetry.

Let B_q denote the block containing state q . Then the minimal DFA M recognizing $L(A)$ is given by:

- $Q_M = \{B_q \mid q \in Q\}$
- $i_M = B_i$

- $F_M = \{B_q \mid q \in F\}$
- $\delta_M(B, a) = B' \in Q_M$ such that $B' \supseteq \{\delta(q, a) \mid q \in B\}$

4.6.3 Example

Identifying indistinguishable pairs of states. This example comes from (Hopcroft *et al.*, 2001, chapter 4). We are going to minimize the automaton shown below.

Figure 4.6: A non-minimal automaton (from Figure 4.8 in Hopcroft *et al.* (2001)).

We need to identify distinguishable states. From the base case, each rejecting state is distinguishable from each accepting state with λ .

Distinguishable pairs (Base Case):

$$\{ (A,C), (B,C), (D,C), (E,C), (F,C), (G,C), (H,C) \}$$

A technical note: in addition to (A,C) the set should include (C,A) as well and similarly for the other pairs. However, we leave out these reflexive pairs for readability.

Next we repeatedly apply the inductive case. For each indistinguishable pair (q, r) , we ask is there $a \in \Sigma$ such that $(\delta(q, a), \delta(r, a))$ is distinguishable? If so, we add (q, r) to the list of distinguishable pairs. For example, consider the pair (A, B) . Since $(\delta(A, 1), \delta(B, 1)) = (F, C)$ and (F, C) is distinguishable, we add (A, B) to the list. On the other hand (A, E) is not added to the list because neither $(\delta(A, 1), \delta(E, 1)) = (F, F)$ nor $(\delta(A, 0), \delta(E, 0)) = (B, H)$ are distinguishable states.

The added ones are shown in bold below.

Distinguishable pairs (Inductive Step 1):

$$\left\{ \begin{array}{l} (A, C), (B, C), (D, C), (E, C), (F, C), (G, C), (H, C) \\ (\mathbf{A}, \mathbf{B}), (\mathbf{A}, \mathbf{D}), (\mathbf{A}, \mathbf{F}), (\mathbf{A}, \mathbf{H}), (\mathbf{B}, \mathbf{D}), (\mathbf{B}, \mathbf{E}), (\mathbf{B}, \mathbf{F}), \\ (\mathbf{B}, \mathbf{G}), (\mathbf{D}, \mathbf{E}), (\mathbf{D}, \mathbf{G}), (\mathbf{D}, \mathbf{H}), (\mathbf{E}, \mathbf{F}), (\mathbf{E}, \mathbf{G}), (\mathbf{E}, \mathbf{H}), \\ (\mathbf{F}, \mathbf{G}), (\mathbf{F}, \mathbf{H}), (\mathbf{G}, \mathbf{H}) \end{array} \right\}$$

At this point, only four pairs of states are not yet known to be distinguishable. These are $\{(A, E), (A, G), (B, H), (D, F)\}$. We repeat the inductive step, to see if any new distinguished pairs are discovered. As before (A, E) is not found to be distinguishable. On the other hand, (A, G) is distinguishable now with string 1 and states F and E are now known to be distinguished. In fact, as a result of this step, only (A, G) is added as shown below.

Distinguishable pairs (Inductive Step 2):

$$\left\{ \begin{array}{l} (A, C), (B, C), (D, C), (E, C), (F, C), (G, C), (H, C) \\ (A, B), (A, D), (A, F), (A, H), (B, D), (B, E), (B, F), \\ (B, G), (D, E), (D, G), (D, H), (E, F), (E, G), (E, H), \\ (F, G), (F, H), (G, H), (\mathbf{A}, \mathbf{G}) \end{array} \right\}$$

The inductive step is repeated again, and this time no new distinguishable states are discovered. Therefore the iteration of the inductive steps terminates.

Distinguishable pairs (Inductive Step 3):

$$\left\{ \begin{array}{l} (A, C), (B, C), (D, C), (E, C), (F, C), (G, C), (H, C) \\ (A, B), (A, D), (A, F), (A, H), (B, D), (B, E), (B, F), \\ (B, G), (D, E), (D, G), (D, H), (E, F), (E, G), (E, H), \\ (F, G), (F, H), (G, H), (\mathbf{A}, \mathbf{G}) \end{array} \right\}$$

Thus, the only indistinguishable pairs are $\{(A, E), (B, H), (D, F)\}$.

Building the minimal automaton. With this information, the states are partitioned into blocks:

$$\left\{ \{A, E\}, \{B, H\}, \{C\}, \{D, F\}, \{H\} \right\}$$

These blocks are the states of the minimal automaton. Since block $\{A, E\}$ contains the start state of the original acceptor, this block is the start state. Since block $\{C\}$ contains a final state of the original acceptor, this block is a final state.

Finally, we calculate the transition function as shown in the diagram below. To illustrate, first Consider the transition from block $\{A, E\}$ upon reading 1. With 1, the original delta function maps state A to F and E to F . There is exactly one block which contains F ; this is the block $\{D, F\}$. Hence the minimal machine transitions from state $\{A, E\}$ to $\{D, F\}$ with 1. The other transitions are determined similarly.

Figure 4.7: The minimal automaton recognizing the same stringset as the one in Figure 4.6.

4.7 Nonregular stringsets

Regular stringsets were defined as those subsets of Σ^* whose membership problem was solvable with a deterministic finite-state acceptor. It was also expressed that finite-state solvable membership problems invoke constant memory. This can be understood to mean that the number of states is constant and does not increase even as the words grow longer and longer.

In this section, we give a few examples of stringsets whose membership problem is not solvable with any DFSA. In each case, I hope to convey that in order to solve the membership problem for any word, the number of states needs to increase as words get longer.

Example 9. Let $\Sigma = \{a, b, c\}$.

1. The set of strings that with each string containing at least as many *as* as *bs*. Formally, we can define this set of strings as follows. For each $a \in \Sigma$ and $w \in \Sigma^*$, let $|w|_a$ be the number of times a occurs in w . So $|aaba|_a = 4$ and $|caca|_c = 2$ and so on. Then the set of strings we are interested in can be expressed as $S_1 = \{w \mid |w|_a \geq |w|_b\}$.
2. The palindrome language. Recall that a palindrome is a word that is the same when written both forwards and backwards. So the palindrome language contains all and only those words that are palindromes. Formally, we can define this set of strings as follows. Let us write w^R to express the reverse of w . So $abac^R = caba$. Then this stringset can be expressed as $S_2 = \{wxw^R \mid w \in \Sigma^*, x \in \{\lambda, a, b, c\}\}$.
3. The $a^n b^n$ stringset. This is pronounced “ a to the n , b to the n ”. Recall that a^n defines the string with a concatenated to itself n times. So $a^4 = aaaa$ and $c^3 = ccc$ and so on. Note $a^0 = \lambda$. So this stringset can be expressed as $S_3 = \{a^n b^n \mid 0 \leq n\}$.

4.7.1 Exercises

Exercise 30. For each of the above examples, we try to write a deterministic finite-state acceptor. This exercise will help us understand why it is impossible.

1. First write an acceptor for S_1 for words up to size 3. Next try to write the acceptor for words up to size 5. What is happening? What information is each state keeping tracking of?
2. First write an acceptor for S_2 for words up to size 2. Next try to write the acceptor for words up to size 4. What is happening? What information is each state keeping tracking of?
3. First write an acceptor for S_3 for words up to size 2. Next try to write the acceptor for words up to size 4. What about up to size 6? What is happening? What information is each state keeping tracking of?

In each case, the information that the states need to keep track of grows as words get longer. This is the basic insight into why the problem of these stringsets (and many like them) cannot be solved with finite-state acceptors.

4.7.2 Formal Analysis

Formal proofs that these are nonregular exist, based on abstract properties of regular stringsets as discussed in (Sipser, 1997; Hopcroft *et al.*, 2001) and elsewhere.

Here is one way to provide a rigorous proof with what we have learned so far.

Recall that when minimizing a DFSA A , we had to determine whether two states did the “same work” or not. We said states did different work, if there was a string that *distinguished* them. A string *distinguishes* state q from r if A would transition to a final state from q but to a non-final state from r (or vice versa). We can use distinguishing strings to see that a DFSA for the above stringsets would have infinitely many states.

Suppose there was a DFSA A for S_1 . Let q_0 be the initial state of A and let $q_a = \delta(q_0, a)$. Now we can ask are there any strings which distinguish q from q_a ? The answer is Yes. The string b distinguishes them because A must transition to an accepting state from q_a with b , but must transition to a non-accepting state from q_0 with b . Thus q_0 and q_a are distinct states.

We can repeat this reasoning. Let $q_{aa} = \delta(q_a, a)$. Is there a string which distinguishes q_{aa} from q_a ? Yes, in fact the string bb distinguishes them because A must transition to an accepting state from q_{aa} with bb , but must transition to a non-accepting state from q_a with bb . So q_a and q_{aa} are distinct states. What about q_{aa} and q_0 ? They are distinct states too as witnessed by the distinguishing string b . So now we have three distinct states.

More generally, define state q_i to be $\delta^*(q_0, a^i)$. For any numbers n, m with $n > m$, one can show that q_n is a distinct state from q_m . We have to find a distinguishing string for these two states. The string b^n is such a string. The DFSA A must transition to an accepting state

from q_n with b^n because the word $a^n b^n$ has at least as many a s as b s. However, A transitions to a non-accepting state from q_m with b^n because the word $a^m b^n$ has more b s as a s since $n > m$. Thus A must have infinitely many states if it is to accept words of arbitrary length. And we haven't even looked at words beginning with bs yet!

Exercise 31. Present an argument like the one above for S_2 and S_3 .

Chapter 5

Tree Acceptors

5.1 Deterministic Finite-state Bottom-up Tree Acceptors

5.1.1 Orientation

This section is about deterministic bottom-up finite-state tree acceptors. The term *finite-state* means that the memory is bounded by a constant, no matter the size of the input to the machine. The term *deterministic* means there is single course of action the machine follows to compute its output. The term *acceptor* means this machine solves *membership problem*: given a set of objects X and input object x , does x belong to X ? The term *tree* means we are considering the membership problem over *treesets*. The term *bottom-up* means that for each node a in a tree, the computation solves the problem by assigning states to the children of a before assigning states to a itself. This contrasts with *top-down* machines which assign states to a first and then the children of a . Visually, these terms make sense provided the root of the tree is at the top and branches of the tree move downward.

Acceptor is synonymous with *recognizer*. *Treeset* is synonymous with *tree language*.

A definitive reference for finite-state automata for trees is freely available online. It is “Tree Automata Techniques and Applications” (TATA) (Comon *et al.*, 2007). The presentation here differs from the one there, as mentioned below.

5.1.2 Definitions

We will use the following definition of trees.

Definition 21 (Trees). *We assume an alphabet Σ and symbols $[]$ not belonging to Σ .*

Base Cases: *For each $a \in \Sigma$, $a[]$ is a tree.*

Inductive Case: *If $a \in \Sigma$ and $t_1 t_2 \dots t_n$ is a string of trees of length n then $a[t_1 t_2 \dots t_n]$ is a tree.*

Let Σ^T denote the set of all trees of finite size using Σ . We also write $a[\lambda]$ for $a[]$.

It will be helpful to review the following concepts related to functions: *domain*, *co-domain*, *image*, and *pre-image*. A function $f : X \rightarrow Y$ is said to have domain X and co-domain Y . This means that if $f(x)$ is defined, we know $x \in X$ and $f(x) \in Y$. However, f may not be defined for all $x \in X$. Also, f may not be *onto* Y , there may be some elements in Y that are never “reached” by f .

This is where the concepts *image* and *pre-image* come into play. The image of f is the set $\{f(x) \in Y \mid x \in X, f(x) \text{ is defined}\}$. The pre-image of f is the set $\{x \in X \mid f(x) \text{ is defined}\}$. So the pre-image of f is the subset of the domain of f where f is defined. The image of f is the corresponding subset of the co-domain of f .

With this in place, we can define our first tree acceptor.

Definition 22 (DFBTA). A Deterministic Bottom-up Finite-state Acceptor (DFBTA) is a tuple (Q, Σ, F, δ) where

- Q is a finite set of states;
- Σ is a finite alphabet;
- $F \subseteq Q$ is a set of accepting (final) states; and
- $\delta : Q^* \times \Sigma \rightarrow Q$ is the transition function. The pre-image of δ must be finite. This means we can write it down—for example, as a list.

We use the transition function δ to define a new function $\delta^* : \Sigma^T \rightarrow Q$ as follows.

$$\begin{aligned} \delta^*(a[\lambda]) &= \delta(\lambda, a) \\ \delta^*(a[t_1 \cdots t_n]) &= \delta(\delta^*(t_1) \cdots \delta^*(t_n), a) \end{aligned} \tag{5.1}$$

There are some important consequences to the formulation of δ^* shown here. One is that δ^* is undefined on tree $a[t_1 \cdots t_n]$ if no transition $\delta(q_1 \cdots q_n, a)$ is defined.

(Also, I am abusing notation since δ^* is strictly speaking not the transitive closure of δ .)

Definition 23 (Treeset of a DFBTA). Consider some DFBTA $A = (Q, \Sigma, F, \delta)$ and tree $t \in \Sigma^T$. If $\delta^*(t)$ is defined and belongs to F then we say A accepts/recognizes t . Otherwise A rejects t . The treeset recognized by A is $L(A) = \{t \in \Sigma^T \mid \delta^*(t) \in F\}$.

The use of the ‘L’ denotes “Language” as treesets are traditionally referred to as *formal tree languages*.

We observe that since the pre-image of δ is finite, there is some n such that for all $(\vec{q}, a, q') \in \delta$, it is the case that $|\vec{q}| \leq n$. In other words, δ is effectively a function from $Q^n \times \Sigma$ to Q . We say δ is n -wide and any DFBTA with an n -wide δ is also called n -wide.

Definition 24 (n -wide Recognizable Treesets). A treeset is n -wide recognizable if there is a n -wide DFBTA that recognizes it.

Definition 25 (Recognizable Treesets). A treeset is recognizable if there exists $n \in \mathbb{N}$, such that an n -wide DFBTA that recognizes it.

5.1.3 Notes on Definitions

We have departed a bit from standard definitions. In particular, most introductions to tree automata make use of a particular kind of alphabet called a *ranked alphabet*. A ranked alphabet Σ_r is a finite alphabet Σ with an arity function $ar : \Sigma \rightarrow \mathbb{N}$. We write $\Sigma_r = (\Sigma, ar)$. The idea is that each symbol comes pre-equipped with a number which indicates how many children it has in trees. This is reasonable provided a node's label determines how many children it can have.

Strictly speaking, a ranked alphabet is not a necessary feature of tree automata. There are two substantive reasons to adopt it. First, using it helps ensure that the transition function is finite. (So it can accomplish the same thing as our requirement that the pre-image of δ be finite.). Second, it can help ensure our transition function is total; that is, defined for every element of the alphabet and the possible states of its children.

A ranked alphabet effectively defines a maximum width n for trees where $n = \max\{ar(a) \mid a \in \Sigma\}$. Thus a DFBTA defined with a ranked alphabet will always recognize a treeset which is a subset of $\Sigma^{T,n}$.

5.1.4 Examples

Example 10. Let $A = (Q, \Sigma, F, \delta)$ with its parts defined as follows.

- $Q = \{q_a, q_b, q_S\}$
- $\Sigma = \{a, b, S\}$
- $F = \{q_S\}$
- $\delta(\lambda, a) = q_a$
- $\delta(\lambda, b) = q_b$
- $\delta(q_a q_b, S) = q_S$
- $\delta(q_a q_S q_b, S) = q_S$

Let us see how the acceptor A processes the two trees below as inputs.

A Lambert graph of this automaton is shown below.

Example 11. The next example regards propositional logic. Propositional logic has one unary operator, negation (\neg), and two binary operators: conjunction (\wedge) and disjunction (\vee). We consider the case with two variables $\{x, y\}$. We can define trees of propositional logic as follows.

- $x[]$ and $y[]$ are trees of propositional logic.
- If A and B are trees of propositional logic, then so are $\neg[A]$, $\wedge[A, B]$, and $\vee[B, A]$.

A Lambert graph of the automata recognizing this language is shown below.

5.1.5 Observations

- For every symbol $a \in \Sigma$ which can be leaf in a tree, you will need to define a transition $\delta(\lambda, a)$.
- For every symbol $a \in \Sigma$ which can have n children, you will need to define a transition $\delta(q_1 \cdots q_n, a)$.

5.1.6 Connection to Context-Free Languages

Recognizable treesets are closely related to the derivation trees of context-free languages.

Theorem 14.

- Let G be a context-free word grammar, then the set of derivation trees of $L(G)$ is a recognizable tree language.
- Let L be a recognizable tree language then $\text{Yield}(L)$ is a context-free word language.

- *There exists a recognizable tree language not equal to the set of derivation trees of any context-free language. Thus the class of derivation treesets of context-free word languages is a proper subset of the class of recognizable treesets.*

5.2 Deterministic Top-down Finite-state Tree Acceptors

5.2.1 Orientation

This section is about deterministic top-down finite-state tree acceptors. The term *finite-state* means that the memory is bounded by a constant, no matter the size of the input to the machine. The term *deterministic* means there is single course of action the machine follows to compute its output. The term *acceptor* means this machine solves *membership problem*: given a set of objects X and input object x , does x belong to X ? The term *tree* means we are considering the membership problem over *treesets*. The term *top-down* means that for each node a in a tree, the computation solves the problem by assigning a state to the parent of a before assigning a state to a itself. This contrasts with *bottom-up* machines which assign states to the children of a first and then a . Visually, these terms make sense provided the root of the tree is at the top and branches of the tree move downward.

Acceptor is synonymous with *recognizer*. *Treeset* is synonymous with *tree language*.

A definitive reference for finite-state automata for trees is freely available online. It is “Tree Automata Techniques and Applications” (TATA) (Comon *et al.*, 2007). The presentation here differs from the one there, as mentioned below.

5.2.2 Definition

Definition 26 (DTFTA). *A Deterministic Top-down Finite-state Acceptor (DTFTA) is a tuple (Q, Σ, F, δ) where*

- Q is a finite set of states;
- q_0 is a initial state;
- Σ is a finite alphabet;
- $\delta : Q \times \Sigma \times \mathbb{N} \rightarrow Q^*$ is the transition function. Note the pre-image of δ is necessarily finite.

The transition function takes a state, a letter, and a number n and returns a string of states. The idea is that the length of this output string should be n . Basically, when moving top-down, the states of the child sub-trees depend on these three things: the state of the parent, the label of the parent, and the number of children the parent has.

We use the transition function δ to define a new function $\delta^* : Q \times \Sigma^T \rightarrow Q^*$ as follows.

$$\begin{aligned} \delta^*(q, a[\lambda]) &= \delta(q, a, 0) \\ \delta^*(q, a[t_1 \cdots t_n]) &= \delta^*(q_1, t_1) \cdots \delta^*(q_n, t_n) \text{ where } \delta(q, a, n) = q_1 \cdots q_n \end{aligned} \quad (5.2)$$

As before, there are some important consequences to the formulation of δ^* . One is that δ^* is undefined on tree $a[t_1 \cdots t_n]$ if transition $\delta(q, a, n)$ does not return a string from Q^* of length n . (Also, I am abusing notation since δ^* is strictly speaking not the transitive closure of δ .)

Definition 27 (Treeset of a DTFTA). *Consider some DTFTA $A = (Q, \Sigma, F, \delta)$ and tree $t \in \Sigma^T$. If $\delta^*(q_0, t)$ is defined and equals λ then we say A accepts/recognizes t . Otherwise A rejects t . Formally, the treeset recognized by A is $L(A) = \{t \in \Sigma^T \mid \delta^*(t) = \lambda\}$.*

The use of the ‘L’ denotes “Language” as treesets are traditionally referred to as *formal tree languages*.

Example 12. Recall the example from last week which generates trees like

- $Q = \{q_a, q_b, q_S\}$
- $\delta(q_a, a, 0) = \lambda$
- $\Sigma = \{a, b, S\}$
- $\delta(q_b, b, 0) = \lambda$
- $q_0 = q_S$
- $\delta(q_S, S, 3) = q_a q_S q_b$
- $\delta(q_S, S, 2) = q_a q_b$

Let us see how the acceptor A processes the two trees below as inputs.

Theorem 15. *Every treeset recognizable by a DTFTA is recognizable, but there are recognizable treesets which cannot be recognized by a DTFTA.*

The following example helps show why this is the case. Consider the treeset T containing only the two trees shown below.

This is a recognisable treeset because the DBFTA below recognizes exactly these two trees and no others.

- | | |
|--------------------------|------------------------------|
| • $Q = \{q, q_S\}$ | • $\delta(\lambda, a) = q_a$ |
| • $\Sigma = \{a, b, S\}$ | • $\delta(\lambda, b) = q_b$ |
| • $q_0 = q_S$ | • $\delta(q_a q_b, S) = q_S$ |
| | • $\delta(q_b q_a, S) = q_S$ |

Notice that this DBFTA fails on these two trees.

A DTFTA cannot recognize the trees in T without also recognizing the trees shown immediately above. This is because moving top down there can only be one value for $\delta(q_S, S, 2)$. Suppose it equals $q_1 q_2$. To recognize the first tree, we would also have to make sure that $\delta(q_1, a, 0)$ and $\delta(q_2, b, 0)$ are defined. Similarly, to recognize the second tree, we would have to make sure that $\delta(q_1, b, 0)$ and $\delta(q_2, a, 0)$ are defined. But it follows then that the aforementioned trees above are also recognized by this DTFTA. For instance the tree with two a leaves is recognized because both $\delta(q_1, a, 0)$ and $\delta(q_2, a, 0)$ are defined. Thus no DTFTA recognizes T .

5.2.3 Observations

- For every symbol $a \in \Sigma$ which can be leaf in a tree, you will need to define a transition $\delta(q, a, 0) = \lambda$.
- For every symbol $a \in \Sigma$ which can have n children, you will need to define a transition $\delta(q, a, n) = q_1 \cdots q_n$.

5.3 Properties of recognizable tree languages

Theorem 16 (Closure under Boolean operations). *The class of recognizable tree languages are closed under union and intersection.*

The class of n -wide recognizable tree languages are closed under union, intersection, and complementation with respect to the $\Sigma^{T,n}$.

The proofs of these cases are very similar to the ones for finite-state acceptors over strings. For every DBFTA A recognizing a treeset T , it can be made *complete* by adding a sink state and transitions to it. Then product constructions can be used to establish closure under union and intersection. Closure under complement is established the same as before too: everything is the same except the final states are now the non-final states of A .

Theorem 17 (Minimal, deterministic, canonical form). *For every recognizable tree language T , there is a unique, smallest DBFTA A which recognizes T . That is, if DBFTA A' also recognizes T then there at least as many states in A' as there are in A .*

5.4 Connection to Context-Free Languages

Recognizable treesets are closely related to the derivation trees of context-free languages.

Theorem 18.

- Let G be a context-free word grammar, then the set of derivation trees $D_T(G)$ is a recognizable tree language.
- There exists a recognizable tree language not equal to the set of derivation trees of any context-free language. Thus the class of derivation treesets of context-free word languages is a proper subset of the class of recognizable treesets.
- Let L be a recognizable tree language then $\text{yield}(L)$ is a context-free word language.

Each of these has a straightforward explanation.

For (1), the recognizable tree language which recognizes $D_T(G)$ for a CFG G can be constructed based on the rules of G . For each symbol a in N , the DBFTA should include $\delta(\lambda, a) = q_a$. And, for each rule $A \rightarrow B_1 \cdots B_n$ in R , the DBFTA should include $\delta(q_{B_1} \cdots q_{B_n}, A) = q_A$. That's it!

For (2), consider the DBFTA A shown below. The claim is that there is no CFG whose derivation language is exactly this recognizable treeset. The only tree in $L(A)$ is (t1), which is shown below A at left. Tree (t2) shows (t1) with the states A assigns to its subtrees.

That no CFG can recognize this treeset follows from the fact that such any CFG G which includes the tree above will need to have the following rules: $S \rightarrow GG$, $G \rightarrow a$, $G \rightarrow b$. But then this G will not only generate (t1) above but also the derivation trees shown below.

Thus $L(A) \neq D_T(G)$.

This example shows that the states of the DBFTA are more abstract than the labels on the nodes. The reason recognizable tree languages are more expressive than the derivation treesets of CFGs follows from this. The DBFTA uses states q_x and q_y to distinguish the subtrees bearing the label G . But the CFG cannot distinguish these trees in this way.

For (3), observe that we can write a CFG that generates the same stringset as the one above. For instance, we could write a CFG with the rule $S \rightarrow ab$.

More generally, though, we can always write a CFG that puts the state information into the nodes themselves. The trees in the derivation treeset for this CFG would be “structurally the same” as the trees in the recognizable treeset, but the labels on the nodes would be different. So they are not the same trees. In the example above for instance we can write a CFG with rules $S \rightarrow G_x G_y, G_x \rightarrow a, G_y \rightarrow b$. There is only one tree in this CFG’s derivation treeset shown below.

Importantly, (t6) is not the same as (t1). The inner nodes are labeled differently! So they are different trees. However, they only differ with respect to how the inner nodes are labeled, so it follows that the stringsets obtained by taking the **yield** of these trees are the same. This is the kind of argument used to show that the yield of any recognizable treeset is a context-free language.
